

## PERCHERON THERAPEUTICS CORPORATE PRESENTATION

**Melbourne, Australia – 18 February 2026:** Percheron Therapeutics Limited (ASX: PER) ('the Company'), an international biotechnology company focused on the development of novel therapies for oncology and rare diseases, is pleased to provide shareholders with a copy of an updated non-confidential corporate presentation. The presentation will be delivered by CEO Dr James Garner at Emergence 2026 Investment Conference to be held today at the Four Seasons Hotel Sydney.

The attached presentation supersedes the corporate presentation released to the market on 5 November 2025 and includes expanded information on the Company's lead program, HMBD-002, together with an updated overview of the Company's financial position following the release of its latest Quarterly Activities report and Appendix 4C.

~ ENDS ~

---

### About Percheron Therapeutics Limited

Percheron Therapeutics Limited [ASX: PER | US OTC: PERCF] is a publicly listed biotechnology company focused on the development and commercialisation of novel therapies for oncology and rare diseases. The company's lead program is HMBD-002, a monoclonal antibody targeting the immune checkpoint regulator, VISTA. HMBD-002 has completed a phase I clinical trial in patients with advanced cancer, which has shown the drug to be generally safe and well-tolerated, and Percheron aims to commence further clinical trials in CY2026.

For more information, please contact [info@PercheronTx.com](mailto:info@PercheronTx.com).

*This announcement has been authorized for release to the Australian Securities Exchange  
by the Board of Directors.*

# Developing a Next Generation Immune Checkpoint Inhibitor for the Treatment of Patients with Cancer

Corporate Overview

February 2026

# Forward-Looking Statements

This presentation contains **forward-looking statements** within the meaning of the safe-harbor provisions such as the Private Securities Litigation Reform Act of 1995. These statements do not relate strictly to historical or current facts and may be accompanied by words such as ‘could,’ ‘would,’ ‘may,’ ‘potentially,’ ‘suggest,’ ‘believes,’ ‘expects,’ ‘should,’ ‘intends,’ ‘plans,’ ‘forecasts,’ and similar words or expressions.

Such statements involve substantial risks and uncertainties, not all of which may be known at the time. All statements contained in this presentation, other than statements of historical fact, including without limitation statements regarding our strategy, research and development plans, collaborations, future operations, future financial position, future revenues, projected costs, pricing, prospects, plans, and objectives of management, are forward-looking statements. Not all forward-looking statements in this presentation are explicitly identified as such.

The Company does not warrant any of the forward-looking statements in this presentation, and investors are advised to interpret such statements in the context of other available sources of information and with the assistance of expert advisors as appropriate.

Many factors could cause the actual results of the Company to differ materially from the results expressed or implied herein, and you should not place undue reliance on the forward-looking statements. Drug development is inherently risky, and only a small proportion of research and development programs lead to a marketed product. Factors which could change the Company’s expected outcomes include, without limitation, our ability to: advance the development of our programs, and to do so within any timelines that may be indicated herein; the safety and efficacy of our drug development candidates; our ability to replicate experimental data; the ongoing validity of patents covering our drug development candidates, and our freedom to operate under third party intellectual property; our ability to obtain necessary regulatory approvals; our ability to enter into and maintain partnerships, collaborations, and other business relationships necessary to the progression of our drug development candidates; changes in the competitive landscape pertaining to our drug development candidates; the timely availability of necessary capital to pursue our business objectives; changes in the public policy environment in one or more countries in which we operate or may seek to operate which disfavour our business; our ability to attract and retain qualified personnel; changes from anticipated levels of customer acceptance of existing and new products and services; and other factors.

Although the Company believes that the expectations reflected in such forward-looking statements are reasonable, and although they reflect our current views as at the date of this presentation, there can therefore be no assurance that such expectations will prove to be correct. The Company has no obligation as a result of this presentation to pursue any specific strategy or plan outlined herein, or to deliver any specific outcome that may be implied or inferred.

Any forward-looking statements contained in this presentation speak only as of the date this presentation is made, and we expressly disclaim any obligation to update any forward-looking statements, whether because of new information, future events or otherwise, except as may be required by law.

# Percheron is developing HMBD-002, a novel, mid-clinical-stage, immuno-oncology therapy with applicability to multiple forms of cancer and high combination potential

## THE SCIENCE

Percheron is developing HMBD-002, a next generation immune checkpoint inhibitor, with the potential to treat many forms of cancer

HMBD-002 targets VISTA, a novel immune checkpoint, similar in many respects to PD-1, the target of Keytruda® (pembrolizumab)

Previous attempts to drug VISTA have been limited by toxicity; HMBD-002 is built on a different antibody scaffold, substantially reducing potential toxicity

HMBD-002 has potential as a monotherapy, but also appears synergistic with other checkpoint inhibitors such as Keytruda®

## THE COMPANY

Percheron is listed on the ASX (ASX: PER), with a market cap of ~\$9 million, and cash at 31DEC25 of ~\$4.5 million

The company trades at a substantial discount to ASX-listed peers, following a corporate transformation during CY2025

Enterprise value largely reflects acquisition cost of HMBD-002 (~\$4.5 million), currently imputing no value to future positive data

Percheron's cash reserves and low burn imply 3.7 quarters of funding

## THE OPPORTUNITY

With phase 1 successfully completed in CY2025, Percheron aims to take HMBD-002 into an international phase 2 human trial in CY2026

US-based phase 1 study, conducted under IND with US FDA, showed very favourable safety profile, both as monotherapy and in combination with Keytruda® (pembrolizumab)

Adaptive, modular phase 2 study design can be launched with very modest cash resources and is designed to provide early validating read-outs

Keytruda® patent expiry in 2028 creates substantial opportunity for novel immune checkpoint inhibitors to expand and extend US\$ ~100 billion market

# Immune checkpoint inhibitors such as HMBD-002 work by reactivating the body's immune response so that it can attack the tumour

- Ordinarily, our immune system protects us against tumour cells in the same way that it protects against bacteria and viruses
- Growing tumours need to inhibit the patient's immune system to avoid being attacked by normal defences
- One of the ways tumours accomplish this is via 'immune checkpoints' such as PD-1 (the target of Keytruda®) and VISTA (the target of HMBD-002)

- Immune checkpoint inhibitors such as HMBD-002 block these inhibitory signals on the surface of the cancer cell
- A number of such immune checkpoint inhibitor drugs have been approved by FDA in recent years, including Keytruda®, Opdivo®, Tecentriq®, Yervoy® and others
- There are not yet any commercial VISTA inhibitors, partly because the target is relatively newly discovered

- Removal of the inhibitory signals allows the body's own immune system to attack the cancer cells
- The reinvigorated immune system can be potent in its own right, but can also work synergistically with other cancer treatments such as chemotherapy and radiotherapy
- In some cancers, inhibiting multiple immune checkpoints is more effective than just one (e.g. PD-1 and CTLA-4 in melanoma)

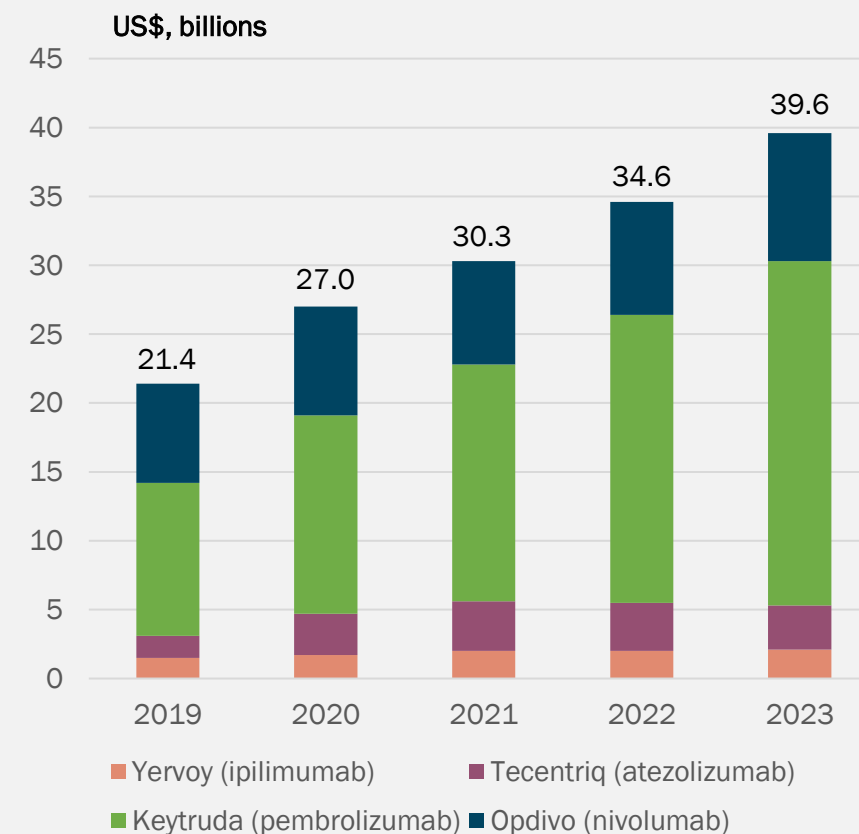

- In addition to making the cancer cells vulnerable to the immune system, VISTA inhibition helps to attract more immune cells into the 'tumour microenvironment,' potentially amplifying its effects by turning 'cold tumours' into 'hot tumours'
- In particular, VISTA inhibition appears to attract myeloid cells, which are less susceptible to other immune checkpoint inhibitors

# Immune checkpoint inhibitors have been one of the fastest growing classes of medicine in the immuno-oncology field, with more than US\$ 40 billion in annual sales

Immuno-oncology therapies target the interaction between tumours and the immune system to enhance the immunological response to cancer

Immuno-oncology has grown to a ~US\$ 40+ billion market

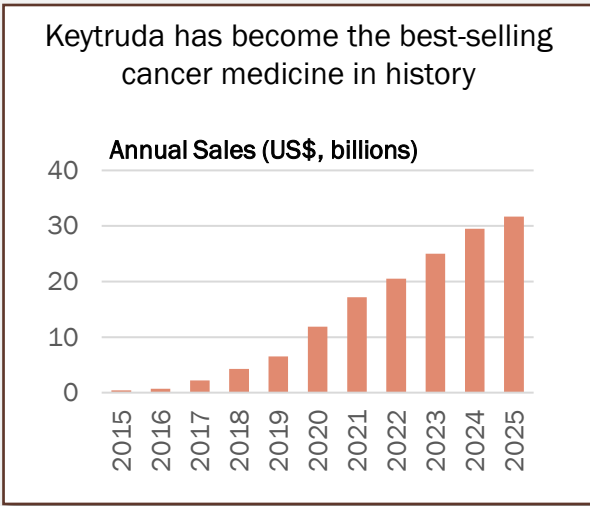

# Keytruda® (pembrolizumab), one of the first-generation immune checkpoint inhibitors, has grown to become the largest cancer product in history

Like Percheron's HMBD-002, Keytruda works by blocking the immune checkpoint on immune cells, so that the tumour cannot 'deactivate' them

Since its first FDA approval in melanoma in 2014, Keytruda has gone on to secure approval in more than a dozen tumours

|                                   |  |
|-----------------------------------|--|
| Melanoma                          | Renal Cell Carcinoma                               |
| Non-Small Cell Lung Cancer        | Endometrial Carcinoma                              |
| Bladder Cancer                    | Triple-Negative Breast Cancer                      |
| Gastric Cancer                    | Merkel Cell Carcinoma                              |
| Oesophageal Cancer                | High Tumour Mutational Burden Cancers (TMB-H)      |
| Cervical Cancer                   | High Microsatellite Instability Cancers (MSI-High) |
| Biliary Tract Cancer              |  |
| Cutaneous Squamous Cell Carcinoma |  |

Although a game-changer, most patients ultimately become unresponsive to Keytruda

|  |   |
|--|---|
| ~40%<br>of melanoma patients never respond | ~30%<br>of responders eventually show disease relapse |
|--|---|

# VISTA is a highly attractive target for novel oncology therapies, showing high expression on many tumours and clear correlation with prognosis

## VISTA is expressed on a wide range of tumours

## High expression of VISTA is associated with worse prognosis

Survival of 85 melanoma patients comparing those with VISTA positive tumour-infiltrating inflammatory cells (TIICs) and those with VISTA negative TIICs

## High VISTA expression is associated with resistance to PD-1 inhibition

Survival of 16 pancreatic cancer patients, all treated with immunotherapy, comparing those with high and low VISTA expression

| Isotype                    | IgG4  | IgG1  | IgG1  | IgG1  | IgG1  |
| Stage                      | Phase I Complete  | Phase I Complete  | Phase I Terminated  | Phase I Terminated  | Phase I Terminated  |
| Exposure to Date           | 48 patients   | 26 patients   | 12 patients   | -   | 33 patients   |
| Combination Data Available | Monotherapy & Combination with Pembrolizumab                                      | Monotherapy   | Monotherapy   | Monotherapy & Combination with Cemiplimab   | Monotherapy & Combination with Pembrolizumab  |
| Status                     | Ongoing   | Inactive  | Discontinued  | Discontinued  | Discontinued  |
| Notes                      |   |   |   | pH-sensitive antibody   |   |

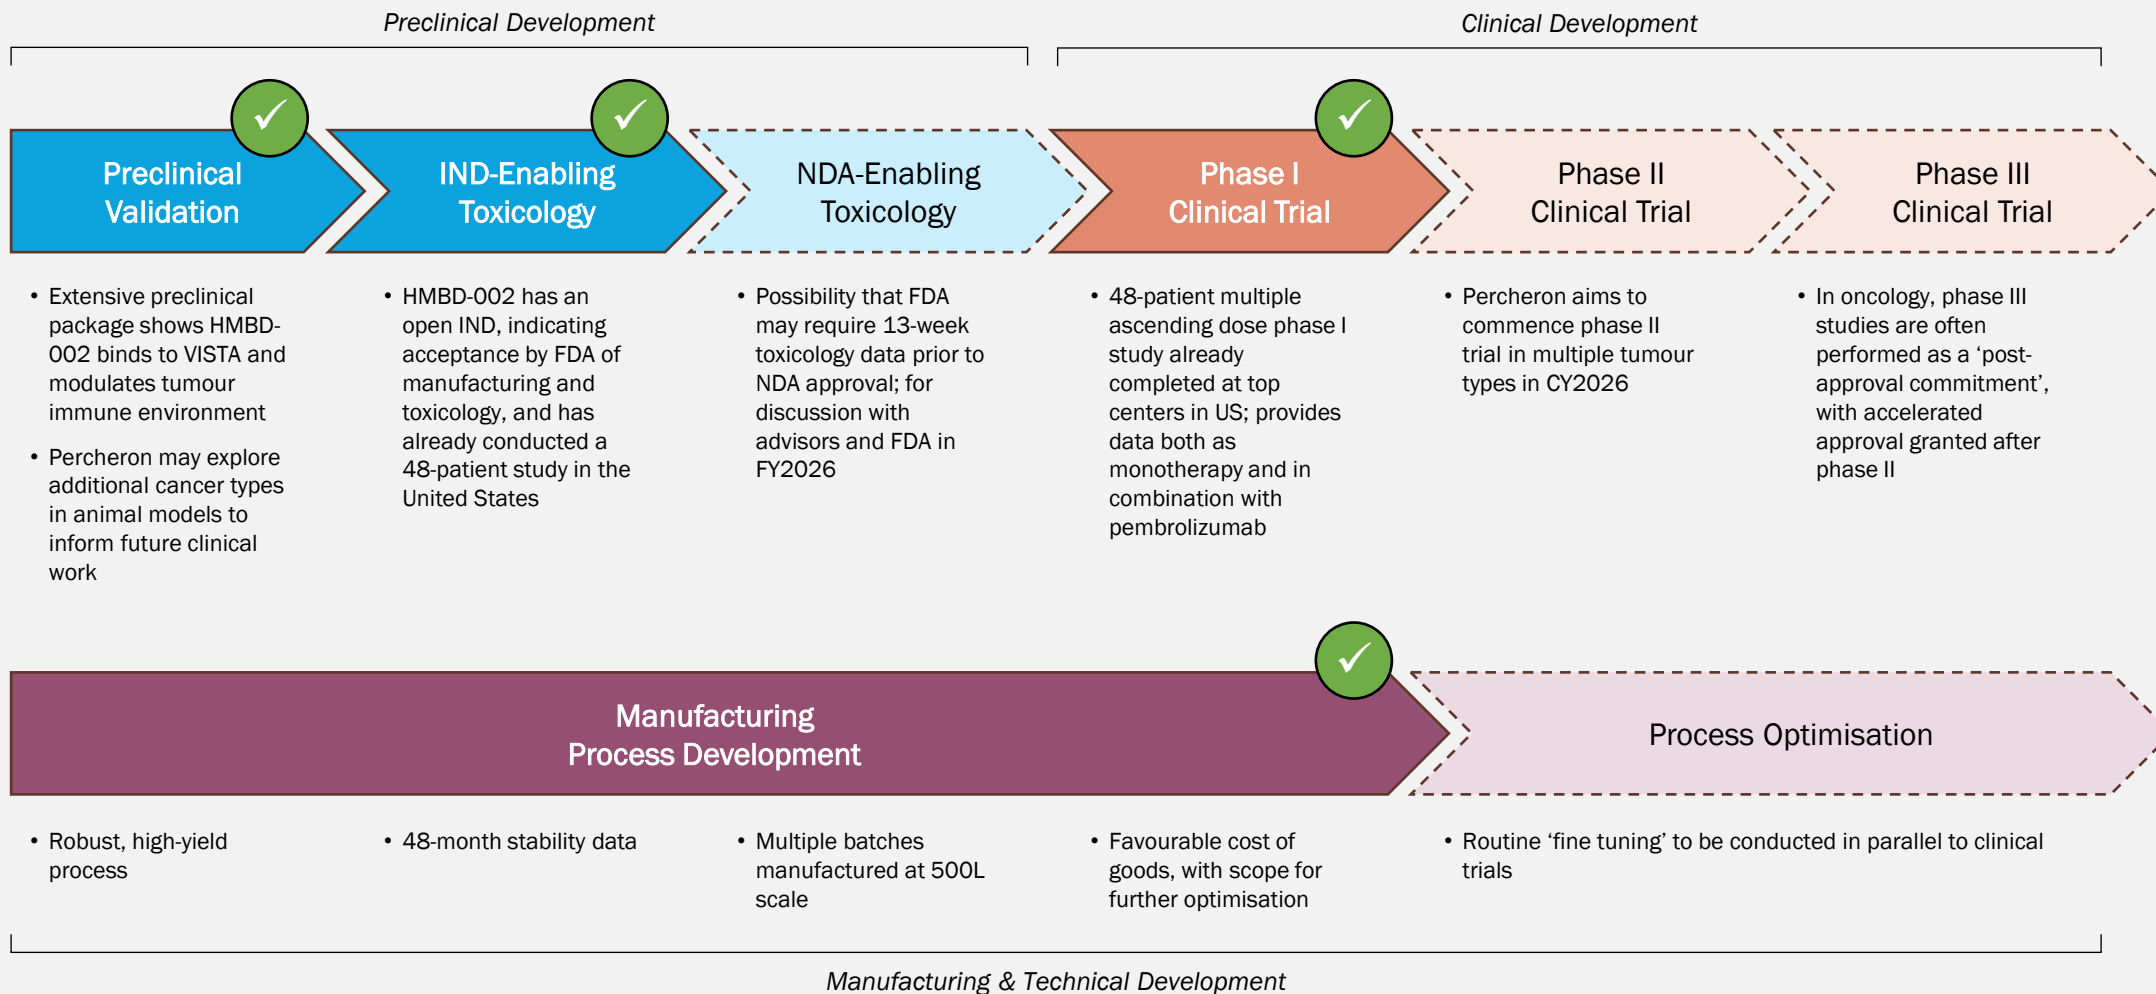

In general, IgG1 antibodies activate antibody-dependent cellular cytotoxicity (ADCC), recruiting immune cells such as natural killer (NK) cells to destroy the target.

This can be a very effective approach in cancer, but can also lead to significant toxicity, including cytokine release syndrome (CRS).

Expert feedback indicates that the key challenge with other VISTA antibodies, which are almost exclusively IgG1, is that they have often proven toxic in clinical trials.

HMBD-002 is an IgG4 antibody, so it blocks VISTA signalling, but does not necessarily destroy VISTA-positive cells. This is likely to make it significantly less toxic in clinical use.

# HMBD-002 is well-advanced in clinical development, with a clear path towards commercialisation

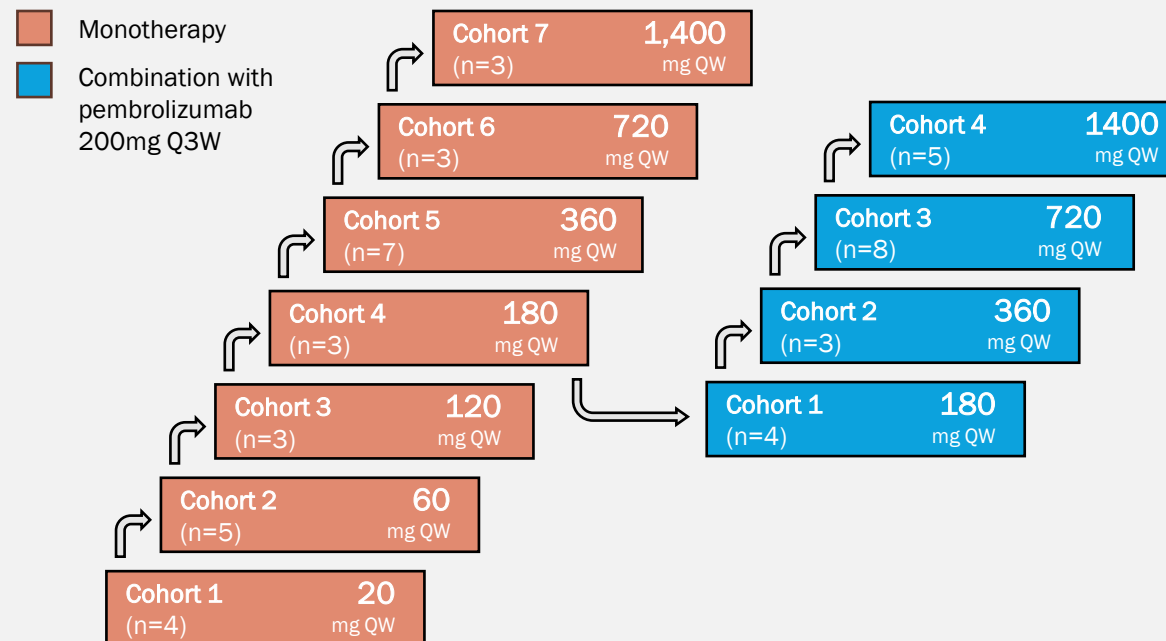

New Drug Application to FDA

# The HMBD-002 phase I study adopted a standard '3+3' design, with an initial monotherapy group (n=28) followed by a pembrolizumab combination group (n=20)

## Patient Population & Study Design

- Advanced cancer patients with no available treatment options known to confer clinical benefit
- ECOG performance status  $\leq 1$
- 3+3 dose escalation design, with a 21-day observation period for dose limiting toxicities
- HMBD-002 administered weekly via 60-minute iv infusion
- 28 patients on monotherapy and 20 patients in combination with pembrolizumab

## Dose Escalation

# Overall response rates such as were seen in this study are common for targeted and cytostatic therapies

## Commentary

- Many targeted therapies have shown similar response profiles in early-phase studies, and some have gone on to become blockbuster commercial products.
- There are several reasons why ORR in phase I sometimes primarily demonstrates a stabilisation effect:
  1. Phase I studies are typically performed in very advanced patients, who may be resistant to almost any therapeutic intervention.
  2. ORR can be a reasonable measure of cytotoxicity and is therefore more useful in the context of cytotoxic chemotherapy, but it often performs less well when measuring the primarily cytostatic effects of targeted therapies.
  3. Immunotherapies in particular can take longer to show benefit, whereas ORR is typically a relatively early-focused measure.

# GLOSSARY

|   |   |   |  |
|---|---|---|--|
| <b>Cold Tumours</b>                         | Tumours with few immune cells in the tumour microenvironment. They are typically relatively resistant to immuno-oncology therapies. Some cancers, such as ovarian cancer and brain cancer, are usually considered to be generally 'cold' tumours. By implicit contrast, a 'hot tumour' or inflammatory tumour is one with a large and active population of immune cells in the tumour microenvironment.   | <b>Overall Survival (OS)</b>                | A measurement of the average time to death from any cause in a clinical trial. When treated patients are compared to a control group, an improvement in OS is considered the 'gold standard' for FDA approval.   |
| <b>Expression</b> (of an immune checkpoint) | In the context of immuno-oncology, a tumour with, on average, a lot of a given immune checkpoint on the surface of its cells is said to highly express that immune checkpoint. For example, a tumour with high PD-1 expression has a lot of PD-1 on the surface of its constituent cancer cells.  | <b>Progression-Free Survival (PFS)</b>      | A measurement of the average time to disease progression (20% increase in size of tumour) or death in a clinical trial. When treated patients are compared to a control group, PFS is often a swifter and more sensitive measure of efficacy than OS, and can often provide a basis for approval.  |
| <b>Immune Checkpoint</b>                    | A control mechanism that allows cells, including tumour cells, to inhibit the local activity of the immune system. Analogous to the brake pedal on a car. Examples of immune checkpoints include PD-1, CTLA-4, LAG3, and VISTA.   | <b>RECIST / Overall Response Rate (ORR)</b> | A standardised way of measuring the early activity of cancer therapies. A complete response (CR) describes 100% reduction in a specific lesion on MRI or CT scan. A partial response (PR) means a 30% or greater reduction in size. Stable disease (SD) means no material change in the size of the tumour. Progressive disease (PD) occurs when a lesion grows by more than 20%. ORR is traditionally a useful way to assess early-stage cancer therapies but rarely provides a basis for FDA approval and is often less sensitive for targeted therapies such as immune checkpoint inhibitors. |
| <b>Immune Checkpoint Inhibitor (ICI)</b>    | A drug which inhibits an immune checkpoint, releasing the 'brake' on the local activity of the immune system. Examples of immune checkpoint inhibitors include Keytruda(R) (pembrolizumab), Opdivo(R) (nivolumab), Yervoy(R) (ipilimumab), and Tecentriq(R) (atezolizumab).   | <b>Resistance</b>                           | In oncology, a tumour is said to be resistant to a given therapy if it does not meaningfully respond to that therapy. Resistance may be primary, if the tumour is unresponsive from the outset, or secondary / acquired if the tumour becomes unresponsive after a period of initially successful treatment.   |
| <b>Ligand</b>                               | Generally, a molecule which connects to another molecule to bring about a biological effect. In the context of immuno-oncology, a ligand is typically the molecule on the immune cell to which the immune checkpoint binds (e.g. PD-1 to PDL-1, CTLA-4 to CD80, LAG3 to Gal3, and VISTA to VSIG-3).   | <b>T-Cell / T-Lymphocyte</b>                | T-cells are one type of cells involved in the immune system. There are many subtypes, and their effects range from control and coordination ('helper T-cells') to direct attack of infectious organisms and cancer cells ('cytotoxic T-cells').  |
| <b>Monoclonal Antibody</b>                  | A class of genetically engineered drugs which utilise the structure of natural human antibodies to generate new molecules which can either block signalling or attack cells. Approximately 40% of cancer drugs are monoclonal antibodies. Monoclonal antibodies are manufactured in living cells under carefully controlled laboratory conditions. They are more challenging to manufacture than 'small molecule' (chemical) drugs but generally simpler than cell therapies. | <b>Tumour Microenvironment (TME)</b>        | The TME includes the tumour itself, along with the surrounding tissues, including structural support ('stroma'), small blood vessels, etc. The TME is typically also infiltrated with immune cells. When considering the immune cells specifically, it is sometimes referred to as the tumour immune microenvironment (TIME).  |
| <b>Myeloid Cells</b>                        | Myeloid cells are one type of cells involved in the immune system. They exert a range of effects, some of which can be immunosuppressive.   | <b>VISTA</b>                                | V-domain immunoglobulin suppressor of T-cell activation. A novel immune checkpoint, first identified in the 2010s, and the target of HMBD-002.   |
