

Bonanza Gold Grades Intersected in Drilling at the Alice River Gold Project

- High-grade gold zones with exceptional continuity intersected in drilling, including zones containing bonanza gold grades:
 - **24m @ 8.0g/t Au** (from 168m) incl. **1.9m @ 87.0g/t Au** (ARDH051)
 - **4m @ 10.3g/t Au** (from 563m) incl. **1m @ 32.8g/t Au** (ARDH050)
- The successful step-out drilling **extends high-grade gold mineralisation a further 120m vertically to over 520m depth** (remains open at depth)
- ARDH050 & ARDH051 are ~160m north of the **spectacular intersection of a 16.4m interval of visible gold¹** recently reported in ARDH061 (results pending)
- Central Target now contains **multiple south-plunging high-grade zones identified from drilling along 400m (to date) of the known 1.5km strike** of the F1a zone (remains open along strike and at depth)
- **Step-out and definition drilling continues on the F1a zone with assay results pending for 13 drill holes**, all of which intersected strong veining and alteration

Pacgold Managing Director Tony Schreck said: "Bonanza intersections of 1.9m @ 87.0g/t Au represent the highest gold grades defined by Pacgold to date on the F1a zone and this particular intersection forms part of a continuous high-grade zone which extends from surface to a depth of 520m, remaining open at depth. Based on the similarities with the Donlin gold model (Tier-1 gold deposit in Alaska), we expect the high-grade zones to continue to extend at depth over a significant vertical distance. This has the potential to contribute materially towards a JORC Resource."

Multiple high-grade zones (or shoots) are now being revealed along a 400m strike length where wide-spaced drilling has so far been completed. The F1a zone is defined over 1.5km which forms a portion of the priority 7km corridor encompassing the Central, Southern and Northern Targets.

Our drilling strategy to date has been focused on the Central Target, where we have achieved exceptional results that provide an excellent opportunity to potentially define a material-sized JORC Resource."

¹ ASX PGO release 08 September 2022. Also note the Company cautions that visual observations of visible gold are not a proxy or substitute for laboratory analysis. Laboratory assays and analysis will be required to confirm the visual interpretations presented in this new release

Pacgold Limited (ASX: PGO) ('Pacgold' or the 'Company') is pleased to provide an update of drilling assay results from the Company's Alice River Gold Project. To date, 26 drill holes (diamond ('DD') and reverse circulation ('RC')) have been completed on the Central Target in the current programme, with assay results pending for 13 drill holes targeting the F1a zone. The current drilling programme of 17,500m is ~60% advanced with 5,472m RC and 5,300m DD completed. Approximately 80% of the drill programme will focus on the F1a zone (Central Target) with the remaining 20% to investigate other areas within the Southern and Northern Targets.

F1a Zone Drilling Update

Assay results for five drill holes are reported here - ARDH045, ARDH047, ARDH050, ARDH051 and ARDH052.

As anticipated, **bonanza-grade gold was intersected in ARDH051** with the occurrence of coarse visible gold in the drill core. ARDH051 targeted the up-plunge projection of the drill intersection of 40m @ 3.0g/t Au incl. 6m @ 17.5 g/t Au (incl. 1m @ 79.1g/t Au which contained visible gold) in ARDH027².

ARDH051 intersected the mineralised zone approximately 60m up-plunge from ARDH027, returning a broad zone containing high-grade gold:

- **24m @ 8.0g/t Au** from 168m
incl. 1.9m @ 87.0g/t Au from 168m
incl. 1.1m @ 136.5g/t Au from 168.8m

The location of ARDH051 is displayed on Figures 1 and 2 (drill cross sections), Figures 3 and 4 (long sections) and Figure 5 (surface drill plan).

The assay results for ARDH051 define excellent continuity of bonanza-grade gold zones over at least 60m distance between ARDH027 and ARDH051. The gold intersections in these holes form part of a larger, continuous, high-grade gold zone containing intersections of 10g/t Au or greater and extending from the base of the shallow historical open pit to a depth of 520m below surface (drill hole ADRH050).

Drill hole ARDH050 represents the deepest hole completed on the project and intersected high-grade gold:

- **4m @ 10.3g/t Au** from 571m
incl. 1m @ 32.8g/t Au from 573m

Refer to Figure 2 (drill cross section) and Figure 4 (long section) for the location of ARDH050.

² ASX PGO release 14 Feb 2022

Step-out drill hole ARDH045 returned high-grade results including:

- **4.7m @ 5.8g/t Au** from 348m
incl. 1m @ 10.6g/t Au from 349m

ARDH045 represents a significant step-out of 200m targeting the down-plunge projection of the drill intersection of 40m @ 3.0g/t Au incl. 6m @ 17.5 g/t Au in ARDH027³ and is located 80m to the south of drillhole ARDH040 and approximately 330m below surface. This drill hole provides excellent early support for the steep southern plunge geometry on the gold system. Refer to Figure 4 (Long section).

Definition drilling is being planned to close up the current wide-spaced drill density and provide data for ongoing refinement of the geological and structural model.

Step-out drill holes ARDH047 and ARDH052 intersected broad zones of veining and alteration with associated gold mineralisation and are interpreted to represent a 'halo' to nearby high-grade mineralisation to the immediate south and potentially to the north. A summary of drill results is presented in Table 2.

The recently reported spectacular zone of visible gold in ARDH061⁴ (over 200 individual visible gold occurrences) within a 16.4m downhole interval is located 160m south of ARDH050 & ARDH051 (latest results are presented in this release). Assay results for ARDH061 are pending and the location of the hole is displayed on Figures 3 and 4 (long sections) and Figure 5 (drill surface plan).

Exploration Model

The application of the Donlin gold model (Tier-1 gold deposit in Alaska) to the project is proving to be very successful. An important aspect of this model is the potential for the high-grade zones to have significant vertical extent, as demonstrated at Donlin. At Alice River, the high-grade zones are now defined over 520m of vertical extent and are open at depth.

The high-grade gold mineralisation observed at the F1a zone is associated with zones of intense multi-phase, hydrothermal quartz veining and brecciation. The current drilling on the Central Target continues to provide strong indications that the F1a zone represents the upper levels of a large-scale, high-grade gold system. Pacgold has identified two primary controlling (north-south trending) structures on the Central Target, being the F1a and the F1b zones (refer to Figure 5). The highest gold grades intersected in drilling occur where broad, north-west trending, 'linking' vein sets intersect the F1a and F1b zones. Drilling to date by Pacgold has concentrated on a 400m section of strike on the 1.5km-long F1a zone where multiple high-grade plunging zones are currently being defined. Repetitions of this structural setting have been identified along the northern extent of the F1a zone and some initial scout drilling has been completed, aimed at locating the intersection of the north-west trending veining corridor with the F1b which is completely concealed by shallow sand cover (results pending). Scout drilling has also been completed on the F1b zone where Pacgold's drilling last year returned 7m @ 3.1g/t Au incl. 2m @ 9.8g/t Au (ARDH031)⁵.

In simpler terms, 'bends' along the main structure are interpreted to potentially represent dilation zones which can focus gold mineralisation. These 'bends' can be seen in the IP geophysics (mapped as resistivity lows), with the best example being at the Central Target (Figure 5).

³ AXS PGO release 14 Feb 2022

⁴ ASX PGO release 08 September 2022. Also note the Company cautions that visual observations of visible gold are not a proxy or substitute for laboratory analysis. Laboratory assays and analysis will be required to confirm the visual interpretations presented in this new release

⁵ ASX PGO release 14 February 2022

It is interpreted that the gross structural setting at the Central Target which controls the distribution of the high-grade gold zones has many similarities to that observed in several large gold deposits, including Fosterville 4.4Moz (Australia) and Waihi 4Moz (New Zealand).

On a regional scale, the structural model for the high-grade mineralisation is being applied to the Southern Target to generate priority targets within the broad gold system ahead of a drilling programme planned for Nov 2022. Further IP geophysics is also planned for the Northern Target ahead of drilling planned for Nov 2022. Wide-spaced IP geophysics is also planned to step out along the main Alice River Shear zone to the north-west and to the south-west, to identify the structure over 10km of potential strike. Pacgold has over 50km of under-explored prospective structure secured under exploration permits (granted EPMs and applications), see Figure 6.

Figure 3: Zoom of Central Target long section along the F1a zone shown in Figure 5

Figure 4: Long section through the Central Target showing the F1a target zone. Location of the long section is shown in Figure 5

Figure 5: Plan showing the drill hole locations on the IP geophysics resistivity image and showing the F1a zone

Next Steps

Two DD rigs plus one RC rig will continue drilling at the project for the next 3 months as part of the current drilling programme, with 80% focus on the Central Target and 20% as part of the Project Pipeline (including Southern and Northern Targets). Drill results for hole ARDH061⁶ (which intersected spectacular visible gold), along with several other holes displaying strong alteration and quartz veining are expected to provide strong news flow in the coming weeks.

IP geophysics is planned on the Northern Target and extensions along the Alice River Shear Zone to the north-west and south-west of the current IP coverage. This work is currently scheduled for Oct 2022.

⁶ ASX PGO release 08 September 2022. Also note the Company cautions that visual observations of visible gold are not a proxy or substitute for laboratory analysis. Laboratory assays and analysis will be required to confirm the visual interpretations presented in this new release

About Pacgold Limited:

Pacgold is an ASX-listed minerals exploration company (ASX: PGO) focussed on the Alice River Gold Project situated at the northern end of the Northeast Queensland Mineral Province. This gold-rich Province contains several multi-million-oz gold deposits including Pajingo, Mt Leyshon, Kidston, and Ravenswood.

Pacgold has a 100% interest in the Alice River Gold Project, covering an historical high-grade goldfield and open-pit mine with eight mining leases and five exploration permits over an area spanning 377km².

Figure 7: Alice River Gold Project regional setting

Competent Persons Statement

The information in this announcement that relates to Exploration Results is based on, and fairly represents, information compiled or reviewed by Mr Geoff Lowe, who is a Member of the Australasian Institute of Mining and Metallurgy. Mr Lowe is the Company's Exploration Manager and holds shares and options in the Company. Mr Lowe has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Lowe consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

APPENDIX 1. JORC CODE TABLE 1 CHECKLIST OF ASSESSMENT AND REPORTING CRITERIA

Section 1: Sampling Techniques and Data

CRITERIA	JORC Code Explanation	Commentary
SAMPLING TECHNIQUES	Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.	- Diamond drilling (DD) and Reverse circulation (RC) drilling was used to obtain samples for geological logging and assaying. - Reverse circulation drilling (precollars) was used to obtain either 1m samples in alteration or 4m composites in unaltered rock. - Diamond core was halved with a core saw through zones where alteration and veining was present and sampled at 1m intervals or at other intervals to match the veining and geology. - The drill holes were sited to test geophysical targets/surfacegeochemical targets as well as previous drilling results
	Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.	1m RC samples were automatically split using a cyclone-mounted cone splitter. 4m RC samples were automatically split as 1m samples using a cyclone-mounted cone splitter, then manually composited to 4m samples using a riffle splitter. The splitter cleaned after each interval with a compressed air gun. - Core and RC samples were submitted to the laboratory and sample preparation consisted of the drying of the sample, the entire sample being crushed to 70% passing 6mm and pulverized to 85% passing 75 microns in a ring and puck pulveriser. All samples are assayed for gold by 50g fire assay with AAS finish. Multielement analysis is completed using an ICP-MS analysis.
	Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.	- Economic gold mineralisation is measured in terms of parts per million and therefore rigorous sampling techniques must be adopted to ensure quantitative, precise measurements of gold concentration. If gold is present as medium – coarse grains, the entire sampling, sub-sampling, and analytical process must be more stringent. - At Alice River, gold can be visible and therefore there may be inherent sampling problems. Procedures used to manage this problem are documented elsewhere in relevant sub-sections of this table.
DRILLING TECHNIQUES	Drill type (e.g., core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g., core diameter, triple or standard tube, depth of diamond tails, face-sampling bit, or other type, whether core is oriented and if so, by what method, etc).	- RC drilling used a 5.5" face sampling RC hammer. - Diamond drilling was all HQ3 (triple tube) drill diameter. - Some core holes were diamond tails using RC pre-collars, othersare diamond drilled from surface. - Orientation gear (diamond drilling) – Electronic digital core orientation system - Survey Gear – Electronic digital multi-shot magnetic survey camera

CRITERIA	JORC Code Explanation	Commentary
DRILL SAMPLE RECOVERY	Method of recording and assessing core and chip sample recoveries and results assessed.	- For diamond core drilling core recoveries are measured by reconstructing core into continuous runs on an angle iron cradle for orientation marking. An average core recovery of greater than 98% has been achieved. - No additional measures were required as core recoveries are deemed to be high and samples considered to be representative. - For RC sample recoveries of less than approximately 80% are noted in the geological/sampling log with a visual estimate of the actual recovery. Very few samples were recorded with recoveries of less than 80%. No wet RC samples were recovered. - No relationship has been observed between sample recovery and grade.
	Measures taken to maximise sample recovery and ensure representative nature of the samples.	Use experienced driller, appropriate drilling fluids and reputable drilling company
	Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.	- Excellent core recovery has been achieved although no study on grade vrs recovery has been undertaken. Consistent sampling of the left-hand side of the split core is undertaken to reduce any bias including when visible gold is encountered. - No relationship has been observed between sample recovery and grade.
LOGGING	Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.	- Geological logging was carried out on all diamond core and RCchips. This included lithology, alteration, sulphide percentages and vein percentages. - For diamond core structure type is recorded along with structural orientation data (alpha and beta measurements) where the drill core is orientated. - Geological logging of alteration type, alteration intensity, vein type and textures, % of veining, and sulphide composition. - All drill core and RC chip trays are photographed.
	Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.	Logging of the core is both qualitative and quantitative in nature
	The total length and percentage of the relevant intersections logged.	All drill holes are logged in full.
SUB-SAMPLING TECHNIQUES AND SAMPLE PREPARATION	If core, whether cut or sawn and whether quarter, half or all core taken.	All the core is half core sampled within zones of visible alteration. Where the core is orientated the left-hand side / half of the core is sampled so that the core orientation line remains in the core tray.
	If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.	RC samples are split using a cyclone mounted rotary cone splitter 87.5%:12.5% on one metre samples. In zones where visual alteration is not present four metre sample composites are created using the one metre sample via a riffle splitter. Compressed air was used to clean the splitter after each sample interval. Duplicated samples were collected in visual ore zones and at a frequency of at least 1 in 20.
	For all sample types, the nature, quality, and appropriateness of the sample preparation technique.	ALS Townville will undertake all the sample preparation and analysis. The methods are considered appropriate.

CRITERIA	JORC Code Explanation	Commentary
	Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.	For RC samples two sub-samples are collected for each 1m interval with duplicate sampling collected at a regular frequency of (1 in 20). For drill core a quarter core sample is collected as duplicate sampling.
	Measures taken to ensure that the sampling is representative of the in-situ material collected, including for instance results for field duplicate/second-half sampling.	Laboratory duplicate sampling has been completed for the Diamond drilling.
	Whether sample sizes are appropriate to the grain size of the material being sampled.	No formal assessment has been undertaken to quantify the appropriate sample size required for good quality determination of gold content, given the nature of the gold mineralisation.
QUALITY OF ASSAY DATA AND LABORATORY TESTS	The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.	Drill core will be analysed by ALS Townsville and analysed by fire assay and AAS finish 50g charge. Multielement analysis was completed by four acid digest with ICP-MS finish. The gold results associated with ARDH007 are based on final gold assays and multielement geochemical results were not finalised at the time of this release.
	For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.	No geophysical tools, spectrometers, or handheld XRF instruments have been used to date to determine chemical composition at a semi-quantitative level of accuracy.
	Nature of quality control procedures adopted (e.g., standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e., lack of bias) and precision have been established.	OREAS standards and blanks are inserted at an approximate frequency of 1 in 15 samples.
VERIFICATION OF SAMPLING AND ASSAYING	The verification of significant intersections by either independent or alternative company personnel.	No verification sampling has been undertaken
	The use of twinned holes.	No twinned holes have been completed
	Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.	- Pacgold collects all logging data in a digital format and the data is combined with project database. Logging data is checked and validated in Micromine 3d software. - Pacgold geologists have verified the digital database from the previous drilling reports and/or original laboratory reports. Digital data has been compiled from quality scanned tables and plans included in the statutory reports. - Pacgold staff have completed field checks and confirmed the location of some drill hole collars and areas of prior gold mining with a standard GPS.
	Discuss any adjustment to assay data.	No adjustments to assay data have been made.
LOCATION OF DATA POINTS	Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.	All PGO drill holes have been surveyed using a DGPS to an accuracy (x,y,z) of <10cm.
	Specification of the grid system used.	The co-ordinate system used in the Pacgold database is MGA zone 54, GDA94 Datum.
	Quality and adequacy of topographic control.	Quality of the topographic control data is poor and is currently reliant on public domain data.

CRITERIA	JORC Code Explanation	Commentary
DATA SPACING AND DISTRIBUTION	Data spacing for reporting of Exploration Results.	Drill hole spacing is generally completed on sections greater than 50m apart
	Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.	- There are no Mineral Resources or Ore Reserves. - The most densely drilled prospect is AQ. With further drilling, data spacing and distribution may support Mineral Resource estimation.
	Whether sample compositing has been applied.	All reported results are part of 1m sample intervals and no sample compositing has been completed.
ORIENTATION OF DATA IN RELATION TO GEOLOGICAL STRUCTURE	Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.	Diamond and RC drilling is completed in an orientation that is perpendicular to the interpreted strike of the mineralised zones.
	If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.	No sampling bias has been identified in connection with the orientation of the drilling.
SAMPLE SECURITY	The measures taken to ensure sample security.	Samples are securely transported by Pacgold staff to a commercial transport Company who transport the samples directly to ALS Townsville.
AUDITS OR REVIEWS	The results of any audits or reviews of sampling techniques and data.	Pacgold has not completed a review of the actual sampling techniques, as this is not possible. Pacgold has reviewed company reports describing sampling techniques. Pacgold has reviewed and where practical validated the database it has compiled.

Section 2: Reporting of Exploration Results

CRITERIA	JORC Code explanation	Commentary
MINERAL TENEMENT AND LAND TENURE STATUS	Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.	- Refer to Solicitor's report in Company's IPO Prospectus released to ASX on 6 July 2021. - The Alice River Gold Project is secured by 13 tenements, including 8 granted Mining Leases (MLs), and 5 Exploration Permits for Minerals (EPMs), for total of approximately 377 square kilometres.
	The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.	Refer to Solicitor's report in Company's IPO Prospectus released to ASX on 6 July 2021. All tenements are in good standing.
EXPLORATION DONE BY OTHER PARTIES	Acknowledgment and appraisal of exploration by other parties.	- Refer to IGR in Company's IPO Prospectus released to ASX on 6 July 2021. A summary of previous exploration and mining is presented below. 1903: Gold mining commenced at Alice River Gold Project. 1903 – 1917: Production of 3,244oz Au at grade of around 38 g/t Au. 1987 – 1998: Cyprus, Beckstar, Golden Plateau, Goldminco and Subloo International completed regional geochemical sampling programmes, rock chip sampling, RAB/auger drilling, airtrack drilling, ground magnetic surveys, IP and VLF-EM geophysical surveys, costeaning programmes, and numerous drilling programmes (RC and diamond drilling). Several estimates of the tonnage and grade of mineralisation, not compliant with the JORC Code were made. 1999 – 2000: A total of 2,745oz gold was produced from 36,000 t of ore by Beckstar. 2001: Beckstar entered Administration and Tinpitch acquired the project. 2017: Spitfire entered a joint venture deal with Tinpitch and completed RC drilling.
GEOLOGY	Deposit type, geological setting, and style of mineralisation.	- The Alice River Gold Project lies within the Alice-Palmer Structural Zone. Gold mineralisation is focused along regional northwest shear zones. The shear zones are largely hosted within the Imooya Granite, a pale grey to white mica-biotite leucogranite (commonly referred in the old reports as an adamellite), of the Siluro-Devonian Kintore Supersuite. At the north end of the Project area the shears intersect gneisses and schists of the Sugarbag Creek Quartzite, which forms the lower part of the Mesoproterozoic Holroyd Metamorphics. - Mineralisation is considered to be Intrusion Related Gold – epithermal style. The gold-bearing shear zones extend episodically for approximately 50 km strike length. Gold mineralisation is generally hosted in quartz veins, and minor quartz breccias, up to 10 – 15 m wide in places. Gold mineralisation is focused in linear zones up to 150 m strike length. - Gold occurs as both fine free-gold in quartz or associated with arsenopyrite and stibnite. Green-white quartz-sericite-epidote alteration zones extend 50 – 70 m around the mineralised veins at some deposits but generally the quartz veins display narrow alteration selvages. The weathered (oxide) zones at surface are around 10 – 20 m deep.
DRILL HOLE INFORMATION	- A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes: - Easting and northing of the drill hole collar.	Drill hole details completed and in progress are presented in Table 1

CRITERIA	JORC Code explanation	Commentary
	– Elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar. – Dip and azimuth of the hole. – Down hole length and interception depth. – Hole length.	
	• If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.	• N/A
DATA AGGREGATION METHODS	• In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g., cutting of high grades) and cut-off grades are usually Material and should be stated.	• Unless specified otherwise, a nominal 0.5g/t Au lower cut-off has been applied incorporating up to 4m of internal dilution below the reporting cut-off grade to highlight zones of gold mineralisation. Refer Table 1 and 2. • Broad lower grader zones described as mineralisation envelopes are reported using a 0.1g/t Au lower cut-off and incorporating up to 6m of internal dilution below the cut-off grade and results are shown in brackets and italics e.g. <i>(50m @ 0.8g/t Au)</i> • No metal equivalent values have been used for reporting exploration results.
	• Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.	• High grade gold intervals internal to broader zones of mineralisation are reported as included intervals. A nominal 10g/t Au cut-off has been applied to reporting high grade gold intervals contained within broader zones of mineralisation. These are routinely specified in the summary results tables.
	• The assumptions used for any reporting of metal equivalent values should be clearly stated.	• No metal equivalents are reported.
RELATIONSHIP BETWEEN MINERALISATION WIDTHS AND INTERCEPT LENGTHS	• These relationships are particularly important in the reporting of Exploration Results. • If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. • If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g., 'down hole length, true width not known').	• The orientation of the drilling is generally perpendicular to the strike of the mineralisation but not perpendicular to the dip on the mineralisation. Generally, the true width of the mineralisation is approximately half the intercept width but until we have additional drilling to confirm the exact geometry of the mineralisation the true width is uncertain.
DIAGRAMS	• Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.	• See body of this ASX announcement for appropriate diagrams.
BALANCED REPORTING	• Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.	• Balanced reporting of Exploration Results is presented.

CRITERIA	JORC Code explanation	Commentary
OTHER SUBSTANTIVE EXPLORATION DATA	Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	- The Alice River Gold Project includes a large amount of exploration data collected by previous companies, including regional stream sediment geochemical data, soil sample and rock chip data, geological mapping data, open hole percussion drilling data, ground magnetics, IP survey data, and costean data. Much of this data has been captured and validated into a GIS database. - Metallurgical tests of selected mineralised samples and tailings dam samples including bottle roll cyanide leach tests were conducted by Golden Plateau in 1994, Goldminco in 1999, and by Tinpitch in 2005 and 2006. Gravity concentration tests were also carried out by Goldminco in 1999. Bottle roll cyanide leach testing work produced variable results. Some samples returned low recoveries, whilst other samples produced high recoveries up to 90%. Further metallurgical work is warranted. - Further information is in the IGR of the Company's IPO Prospectus released to ASX on 6 July 2021.
FURTHER WORK	The nature and scale of planned further work (e.g., tests for lateral extensions or depth extensions or large-scale step-out drilling).	Further drilling RC and diamond is planned.
	Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.	See body of this ASX announcement.
